

## Basic Syntax and Types

### Syntax Fundamentals

<b>Function Definition</b>	<pre>functionName :: Type1 -&gt; Type2 -&gt; ReturnType  functionName arg1 arg2 =   expression</pre> <p>Example:</p> <pre>add :: Int -&gt; Int -&gt; Int add x y = x + y</pre>
<b>Comments</b>	<pre>-- Single-line comment {- Multi-line   comment -}</pre>
<b>Layout</b>	Haskell uses indentation to define blocks. Consistent indentation is crucial.
<b>Let Bindings</b>	<pre>let   variable = expression in   resultUsingVariable</pre>
<b>Where Bindings</b>	<pre>functionName arg1 arg2 =   result   where     variable = expression</pre>
<b>Case Expressions</b>	<pre>case expression of   pattern1 -&gt; result1   pattern2 -&gt; result2   _         -&gt; defaultResult</pre>

### Basic Data Types

<b>Int</b>	Integer values with a fixed range. Example: <code>5</code> , <code>-10</code>
<b>Integer</b>	Integer values with arbitrary precision. Example: <code>12345678901234567890</code>
<b>Float/Double</b>	Floating-point numbers. Example: <code>3.14</code> , <code>2.718</code>
<b>Bool</b>	Boolean values: <code>True</code> or <code>False</code>
<b>Char</b>	Single Unicode characters. Example: <code>'a'</code> , <code>'\n'</code>
<b>String</b>	List of characters. Example: <code>"Hello, World!"</code>

### Type Signatures

<p>Explicit type signatures are recommended for clarity.</p> <pre>variable :: Type functionName :: Type1 -&gt; Type2</pre> <p>Example:</p> <pre>x :: Int x = 5  add :: Int -&gt; Int -&gt; Int add x y = x + y</pre>
--

## Functions and Control Flow

### Function Application

<b>Basic Application</b>	<p>Functions are applied by simply placing arguments after the function name.</p> <pre>functionName arg1 arg2</pre> <p>Example:</p> <pre>add 3 5 -- Result: 8</pre>
<b>Parentheses</b>	<p>Parentheses are used to control precedence.</p> <pre>functionName (arg1 + arg2)</pre>
<b>Composition</b>	<p>Function composition using <code>.</code></p> <pre>(f . g) x -- Equivalent to f            (g x)</pre>

## Control Flow

<b>If-Then-Else</b>	<pre>if condition then expression1 else expression2</pre> <p>Example:</p> <pre>if x &gt; 0 then "Positive" else "Non-positive"</pre>
<b>Guards</b>	<p>Guards provide an alternative to if-then-else for defining functions.</p> <pre>functionName arg1   condition1 = expression1   condition2 = expression2   otherwise = defaultExpression</pre> <p>Example:</p> <pre>absVal x   x &gt;= 0 = x   otherwise = -x</pre>
<b>Case Expressions</b>	<p>Pattern matching with <code>case</code>.</p> <pre>case expression of pattern1 -&gt; result1 pattern2 -&gt; result2 _         -&gt; defaultResult</pre>

## Lambda Expressions

<p>Anonymous functions defined using <code>\</code>.</p> <pre>\arg1 arg2 -&gt; expression</pre> <p>Example:</p> <pre>(\x y -&gt; x + y) 3 5 -- Result: 8</pre>
--

## Data Structures

### Lists

<b>List Syntax</b>	<pre>[element1, element2, element3]</pre> <p>Example:</p> <pre>[1, 2, 3, 4, 5]</pre>
<b>Cons Operator</b>	<p>The <code>(:)</code> operator adds an element to the beginning of a list.</p> <pre>head : tail</pre> <p>Example:</p> <pre>1 : [2, 3] -- Result: [1, 2, 3]</pre>
<b>List Comprehension</b>	<pre>[expression   variable &lt;- list, condition]</pre> <p>Example:</p> <pre>[x * 2   x &lt;- [1..5], x `mod` 2 == 0] -- Result: [4, 8]</pre>
<b>Common Functions</b>	<pre>head, tail, length, map, filter, foldl, foldr</pre>

### Tuples

<b>Tuple Syntax</b>	<pre>(element1, element2, element3)</pre> <p>Example:</p> <pre>(1, "hello", True)</pre>
<b>Accessing Elements</b>	<pre>fst</pre> (for 2-tuples), <pre>snd</pre> (for 2-tuples) For larger tuples, pattern matching is typically used.

### Data Type Declarations

<pre>data MyType = Constructor1 Type1   Constructor2 Type2 Type3</pre> <p>Example:</p> <pre>data Color = Red   Green   Blue data Shape = Circle Float   Rectangle Float Float</pre>
---

## Typeclasses and Monads

## Typeclasses

<b>Defining a Typeclass</b>	<pre>class MyTypeclass a where   myFunction :: a -&gt;   ReturnType</pre>
<b>Instances</b>	<pre>instance MyTypeclass MyType   where   myFunction arg = expression</pre>
<b>Common Typeclasses</b>	<code>Eq</code> , <code>Ord</code> , <code>Show</code> , <code>Read</code> , <code>Num</code> , <code>Functor</code> , <code>Applicative</code> , <code>Monad</code>

## Monads

<b>Monad Typeclass</b>	<pre>class Monad m where   return :: a -&gt; m a   (&gt;&gt;=) :: m a -&gt; (a -&gt; m b)   -&gt; m b</pre>
<b>Do Notation</b>	Syntactic sugar for working with Monads. <pre>do   x &lt;- action1   y &lt;- action2 x   return (x + y)</pre>
<b>Common Monads</b>	<code>Maybe</code> , <code>IO</code> , <code>List</code> , <code>Either</code>

## IO Monad

Used for performing input/output operations.

```
main :: IO ()
main = do
  line <- getLine
  putStrLn ("You entered: " ++ line)
```
