

AWK Basics

Syntax

<code>awk 'pattern { action }' file</code>
AWK scripts consist of patterns and actions. For each line in the input <code>file</code> , AWK checks if the <code>pattern</code> matches. If it does, the <code>action</code> is executed. If no pattern is given, the action is performed for every input line. If no action is given, the matching line is printed.
<code>awk '{ print \$1 }' file</code>
Prints the first field of each line in <code>file</code> . Fields are separated by whitespace by default.
<code>awk -F',' '{ print \$1, \$2 }' file</code>
Uses <code>,</code> as the field separator and prints the first and second fields of each line.
<code>awk 'BEGIN { print "Start" } { print \$0 } END { print "End" }' file</code>
<code>BEGIN</code> block is executed before processing any input. <code>END</code> block is executed after processing all input. The <code>{ print \$0 }</code> action prints each line of the input file.

Variables and Operators

Built-in Variables

<code>\$0</code>	The entire current line.
<code>\$1</code> , <code>\$2</code> , ...	The first, second, ... field of the current line.
<code>NF</code>	The number of fields in the current line.
<code>NR</code>	The number of the current line.
<code>FILENAME</code>	The name of the current input file.
<code>FS</code>	The field separator (default is whitespace). Can be changed with <code>-F</code> option or by assigning a value to <code>FS</code> .
<code>RS</code>	The record separator (default is newline).
<code>OFS</code>	The output field separator (default is whitespace).
<code>ORS</code>	The output record separator (default is newline).

Functions

Patterns

<code>BEGIN</code>	Executed before any input is read.
<code>END</code>	Executed after all input is read.
<code>expression</code>	A boolean expression that determines whether the action is executed. Example: <code>\$1 > 10</code>
<code>pattern1, pattern2</code>	A range pattern that matches all lines from a line matching <code>pattern1</code> to a line matching <code>pattern2</code> .
<code>!pattern</code>	Negates the pattern. The action is executed if the line does <i>not</i> match the pattern.

Actions

<code>print</code>	Prints the current line or specified fields. Example: <code>print \$1, \$3</code>
<code>printf</code>	Formatted printing, similar to C's <code>printf</code> . Example: <code>printf "%s: %d\n", \$1, \$2</code>
<code>next</code>	Skips the current line and proceeds to the next input line.
<code>exit</code>	Terminates the AWK script.
<code>delete array[index]</code>	Deletes an element from an array.

Operators

<code>=</code>	Assignment operator.
<code>==</code> , <code>!=</code>	Equality and inequality operators.
<code>></code> , <code><</code> , <code>>=</code> , <code><=</code>	Comparison operators.
<code>~</code> , <code>!~</code>	Regular expression match and non-match operators.
<code>&&</code> , <code> </code> , <code>!</code>	Logical AND, OR, and NOT operators.
<code>+</code> , <code>-</code> , <code>*</code> , <code>/</code> , <code>^</code> , <code>%</code>	Arithmetic operators: addition, subtraction, multiplication, division, exponentiation, modulus.
<code>++</code> , <code>--</code>	Increment and decrement operators.
<code>+=</code> , <code>-=</code> , <code>*=</code> , <code>/=</code> , <code>%=</code> , <code>^=</code>	Compound assignment operators.

User-defined Variables

Variables can be defined and used within AWK scripts. Example: <pre>BEGIN { count = 0 } { count++ } END { print "Total lines:", count }</pre>
Variables are initialized to zero or the empty string if not explicitly initialized.

Built-in Functions

<code>length(string)</code>	Returns the length of the string.
<code>substr(string, start, length)</code>	Returns a substring of the string starting at <code>start</code> with the given <code>length</code> .
<code>index(string, substring)</code>	Returns the starting position of <code>substring</code> in <code>string</code> , or 0 if not found.
<code>split(string, array, separator)</code>	Splits the string into elements of the <code>array</code> using <code>separator</code> as the delimiter. Returns the number of elements.
<code>match(string, regex)</code>	Returns the starting position of the regular expression <code>regex</code> in <code>string</code> , or 0 if not found. Sets <code>RSTART</code> and <code>RLENGTH</code> .
<code>gsub(regex, replacement, string)</code>	Globally substitutes all matches of the regular expression <code>regex</code> in <code>string</code> with <code>replacement</code> . Returns the number of substitutions made.
<code>tolower(string)</code>	Converts the string to lowercase.
<code>toupper(string)</code>	Converts the string to uppercase.
<code>sprintf(format, expr1, expr2, ...)</code>	Formats expressions <code>expr1</code> , <code>expr2</code> , ... according to the format string <code>format</code> (similar to C's <code>sprintf</code>).

Examples

Simple Examples

Print lines longer than 80 characters:	<code>awk 'length(\$0) > 80 { print }' file</code>
Print the total number of fields in the input:	<code>awk '{ total += NF } END { print "Total fields:", total }' file</code>
Print lines containing the word 'error':	<code>awk '/error/ { print }' file</code>
Print the last field of each line:	<code>awk '{ print \$NF }' file</code>

User-Defined Functions

You can define your own functions in AWK.

Syntax:

```
function function_name(parameter1, parameter2, ...) {  
    # Function body  
    return value  
}
```

Example:

```
function max(x, y) {  
    return (x > y ? x : y)  
}  
  
{ print max($1, $2) }
```

Advanced Examples

Calculate the average of the values in the first field:	<code>awk '{ sum += \$1; count++ } END { if (count > 0) print "Average:", sum / count }' file</code>
Print unique lines in a file:	<code>awk '!seen[\$0]++' file</code>
Sum values in a specific column based on a condition:	<code>awk '\$2 == "active" { sum += \$1 } END { print "Sum of active values:", sum }' file</code>
